# Material recognition in the wild with the Materials in Context Database (Supplemental Material) 

Sean Bell* Paul Upchurch* Noah Snavely Kavita Bala<br>Department of Computer Science, Cornell University<br>\{sbell, paulu, snavely,kb\}@cs.cornell.edu

## 1. Overview

In the supplemental material, we present details omitted from the main paper. We present details on:
the interface for our AMT tasks in Section 2,
counts of our train/val/test sets in Section 3,
single patch classifications results our near-duplicate method detailed FMD results the full list of results in Section 4, in Section 5, in Section 6, and in Section 7.

Our dataset, Materials in Context Database (MINC), is fully public and hosted online at http://minc.cs.cornell.edu/, which includes all data, dataset splits, and trained models, so that other researchers can reproduce our experiments.

## 2. Crowdsourcing tasks

In this section, we provide some more detail on our crowdsourcing tasks (Section 3.2 in the main paper). Figures 1,2 , and 3 show screenshots of our three-stage Amazon Mechanical Turk pipeline. We build all of our crowdsourcing infrastructure on top of the publicly available OpenSurfaces platform [1].

Stage 1: filter by photo. In Stage 1 (Figure 1), we determine which materials each photo contains. We enumerate all combinations of photos and materials, so that each photo is considered for all materials. Since this results in a large number of combinations to test, and we do not need high quality responses, we only ask a single worker per photo. We found it was important to include this stage, since workers in the next stage would get frustrated if they were asked to localize too many materials that aren't present in the photo.

Stage 2: localize materials. In Stage 2 (Figure 2), workers are shown photos that were selected by a worker in stage 1 , and they are asked to click on three points in that image

[^0]

Figure 1: Stage 1: filter by photo. Workers select which images (out of 40) contain a given substance.
that have a given material. Since there are many false positives from stage 1 , they can advance to the next photo after clicking on any number of points, including zero points. Only one worker labels each photo-material combination.

Initially, we found that the submissions were surprisingly high quality, and thus we approved all submissions immediately and did not include sentinels. After collecting most of the data, we discovered that some workers had taken advantage of our lack of quality controls in this stage. However, we were able to detect these workers and exclude their submissions by measuring the fraction of responses that agree with Stage 3 (described next).

Stage 3: verify. In Stage 3 (Figure 3), we verify the responses from Stage 2 by asking new workers to re-label all points without revealing the original prompts from Stage 2. Thus, if a worker in Stage 3 can select the correct material from a long list and agree with the worker from Stage 2, then we consider the material label to be sufficiently accu-

Figure 2: Stage 2: localize materials. Workers localize materials by clicking on 3 points in the image that contain a given material. In this example, workers have selected 3 points highlighted with red cross-hairs (zoom in to better see the selected points).

Figure 3: Stage 3: verify. Workers localize materials by clicking on 3 points in the image that contain a given material.
rate. If the stages disagree, then we discard the point.
Since we found that workers would avoid responding with "Not on list" or "I can't tell", we collected a larger list of possible material names than the other two stages. If workers select any of these extra material names, it is as if they had selected "Not on list".

Material categories. When initially collecting responses, we collected a wider range of material categories than what was used for material recognition. We attempted to split
some categories into more fine-grained categories such as "Plastic - clear" and "Plastic - opaque". However, we found that such splits introduced disagreements between workers, which led to many points being rejected (points are only kept if workers can agree on the category). Further, some categories are genuinely confusing (such as laminate countertops designed to look like another stone). Thus, we grouped categories together and re-computed worker agreement with the coarser set of categories.

## 3. Sample distribution

From labeled clicks and segments we get a large set of patch centers. Each patch center is a sample for the learning system. Our goal is to randomly split our samples into train/val/test in ratios of 84/6/10. However, it is also necessary to ensure there are enough individual segments in the test set so that segment accuracy can be evaluated for fullscene material classification. In addition we wanted to balance the distribution across category, photo source (Houzz versus Flickr) and sample source (click versus segment).

Splits were created by gathering samples into clusters based on near-duplicate detection. The statistics of each cluster were computed and placed into a matrix where rows are clusters and columns are the cluster statistics. The matrix rows were randomly shuffled and two indices were found which split the set into ratios of 84/6/10. Then rows were greedily exchanged to satisfy constraints: (i) at least 75 segments per category in test, (ii) every measured statistic is strictly positive. A split is scored by the magnitude of the relative error of train and validate against test. This process was repeated several times and the split with lowest relative error was taken. Detailed counts of the split used in all experiments are shown in Table 1.

## 4. Patch classification

In Figure 4 we present a confusion matrix of single patch classifications with GoogLeNet (test set). The matrix has been normalized so that rows sum to $100 \%$. Notable confusions are: $8.2 \%$ of brick predicted as stone, $8.2 \%$ of mirror predicted as painted, $5.7 \%$ of mirror predicted as glass, $5.9 \%$ of paper predicted as plastic, $5.9 \%$ of plastic predicted as ceramic, and $5.6 \%$ of leather predicted as fabric.

In Figure 5 we present a visualization of the preceding confusion matrix. Each cell of the matrix has been visualized by 16 patches whose true labels and predicted labels correspond to that entry of the matrix. (patches selected randomly). Since correct classifications only appear in the diagonal, the visualization, by design, shows many more incorrect classifications than correct ones.

In Figure 7 we present a larger version of Figure 7 from the main paper with each category identified. See Section 5.1 of the main paper for a description.

## 5. Near-duplicate detection

To detect near-duplicates (Section 4.1 of the main paper), we compute AlexNet fc6 features for all images. We normalize the features, project them down to 1024 dimensions using PCA, and then re-normalize them. Two normalized features $f_{1}$ and $f_{2}$ are considered to be duplicates if:

$$
f_{1} \cdot f_{2} \geq 0.9
$$

To ensure we don't miss any duplicates, we perform all $O\left(n^{2}\right)$ comparisons brute-force. See Figure 6 for example clusters of near-duplicate images.

## 6. FMD experiments

We found that combining a pretrained AlexNet with the approach of [2] exceeds both a finetuned AlexNet and the best reported result of [2]. Specifically, we take the reference BVLC AlexNet model, classify each image (warped to be square) with 15 x oversampling (scales: $\{0.5, \sqrt{0.5}, 1\}$, crops: center and corners). The mean fc7 vector is extracted (4096 dim). Using the publicly available code of [2], Fisher vectors were concatenated with mean fc7 vectors and a classifier was trained with stochastic dual coordinate ascent linear SVM ( $\lambda=0.0002$ ) on 10 random splits ( 500 training samples, 500 testing). As shown in Table 2, the combination of AlexNet and Fisher vectors was superior to either feature alone. It was also better than finetuning AlexNet ( 5 folds, 700/100/200 train/validate/test samples, trained as described in Section 4.1 of the main paper, tested with oversampling).

For all $\pm$ uncertanties (both in Table 2 and in the main paper), we report the uncertainty of the mean (i.e., $\sqrt{\operatorname{stdev}} / N$ where $N$ is the sample count) rather than standard deviations.

| Classifier | Features | Mean Accuracy | Trials |
| :---: | :--- | :--- | :---: |
| Linear SVM | fv | $59.3 \pm 0.5 \%$ | 14 splits |
| Linear SVM | fc7 | $62.5 \pm 0.4 \%$ | 14 splits |
| AlexNet |  | $66.5 \pm 1.5 \%$ | 5 folds |
| Linear SVM | fv+fc7 | $69.6 \pm 0.3 \%$ | 10 splits |

Table 2: FMD mean class accuracy of a finetuned AlexNet and a linear SVM with combinations of pretrained AlexNet (fc7) and Fisher vector (fv) features. For comparison, the previous best is 67.1 ("Combined" features of [2]).

Figure 6: Example clusters of near-duplicate images.

Figure 7: Patch accuracy with varying patch scale. Dots: peak accuracy for each category. CNN: AlexNet.

Figure 4: Confusion matrix for patch-based classification with GoogLeNet, trained with patch scale $23.3 \%$. Rows are ground truth; columns are predictions. The mean class accuracy is $85.22 \%$ on test. The patch visualized to the left of each row is the patch in that category which is classified correctly with the highest confidence.

Figure 5: Visualization of the patch classification confusion matrix. Each cell of the confusion matrix has been visualized by 16 random patches. Rows are ground truth, columns are predicted labels. Test set patches were classified with GoogLeNet.

Table 3: Parameter settings for our dense CRF; see Section 4.2 of the main paper for explanations of these parameters. The CRF IDs are renumbered so that better performing parameter values have a lower ID number. Table headers: CRF ID: unique identifier for this configuration (used in later table); $w_{p}$ : pairwise weight (note that setting $w_{p}=0$ is equivalent to not using a CRF); $\theta_{p}$ : position feature scale (dimensionless); $\theta_{L}$ : color intensity feature scale (has units of $L^{*}$ from the $L^{*} a^{*} b^{*}$ colorspace); $\theta_{a b}$ : color chromaticity feature scale (has units of $a^{*}$ or $b^{*}$ from the $L^{*} a^{*} b^{*}$ colorspace); While we explored a more extensive set of parameter values on the validation set, this is the smaller smaller set of parameters for our final evaluation. This was necessary to keep runtimes manageable.

## 7. Material segmentation and recognition experiments

As mentioned in Section 5.2 of the main paper, we tried a variety of CNN configurations (listed in Table 4), as well as a variety of CRF parameter settings (Table 3). The final end-to-end segmentation and recognition system involves several decisions: which CNNs to combine, how to average them, and which CRF parameters to use. We enumerated a large number of combinations, listed in the table below. For each row, we measure accuracy across the entire validation set; these are not test accuracies. We report test accuracies in Table 4 of the main paper.

Note that the different measures of accuracy lead to very different rankings (entries within $1 \%$ of the max are highlighted in bold). This is illustrated visually in Figure 9 of the main paper.

Table 5: (Below, multi-page) Exhaustive list of CNN and CRF configurations, measured on the validation set, sorted by mean class accuracy across segments (first column). Table headers: S. Cls: mean class accuracy measured on segments (i.e. the pixels in each segment); S. Tot: total accuracy measured on segments (also known as "per-pixel accuracy"); C. Cls: mean class accuracy on click locations; C. Tot: total accuracy measured on click locations; CNNs: list of CNNs (each ID can be found in Table 4); Op: whether the different CNN predictions are averaged using a sum or a product (geometric average), CRF: the CRF parameter ID (each ID can be found in Table 3).

Table 4: (Above) Configurations of CNNs used for material segmentation and recognition. In all configurations, when there are multiple predictions from different scales or shifts or mirrors, the resulting outputs are averaged together (with arithmetic average). Table headers: CNN ID: unique identifier for this configuration (used in later table); Min dim: smaller dimension of the input photo (this scales the effective patch size, since each prediction has a fixed receptive field of $227 \times 227$ pixels); \# shifts: number of partial strides (\# shifts $=1$ corresponds to 32 px strides, \# shifts $=2$ corresponds to 16 px strides).
